Introduction to Astroparticle Physics

Michael Prouza

Center for Particle Physics Institute of Physics Academy of Sciences of the Czech Republic Prague

"Astrophysics in the 21st century will mainly concentrate on two fundamental problems. The first problem is something we would like to see, but we don't see. This something is dark matter. And the second problem is something we don't want to see. but we unfortunately observe. In this second case I mean ultra-high energy cosmic rays."

David N. Schramm

Outline

• History

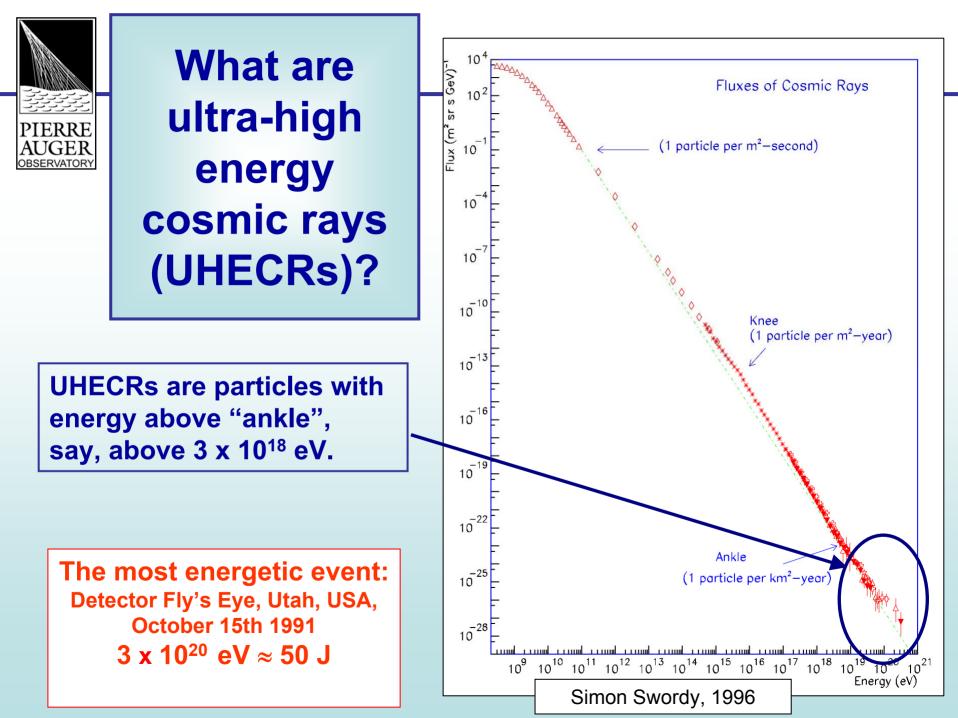

- Previous experiments
 - AGASA vs. HiRes contradiction
- Physics background
 - GZK cutoff
 - Magnetic fields
- Pierre Auger Observatory
- New results
 - Spectrum
 - Composition
 - Photon limit, neutrino limit
 - Hadronic models
 - Anisotropy

Outline II

Astroparticle physics (intersection between particle physics, astrophysics and cosmology) explores also many other parts of fundamental physics:

- similar technique (as for CR) different energy range: imaging atmospheric Cherenkov telescopes (gamma-rays)
- detectors in ice, water, salt, etc.:
 high energy neutrinos
- dark matter detection
- detectors of gravitational waves

Extensive air showers

time=-266µs

• Primary particle interacts with atmosphere

- Number of secondary particles is created
- Secondaries interact again, and again, ...
- Typical shower 10²⁰ eV: 10¹⁰ particles at ground
- Animation color code:

blue: electrons/positrons cyan: photons orange: protons red: neutrons gray: mesons green: muons

How to detect UHECRs?

Primary particle coming from space (proton or light nucleus) hits the atmosphere of the Earth

• The number of secondary particles is proportional to energy of primary particle

 Relative time of detection of individual secondary particles carries information about incident direction of primary particle

• Types of detectors: ground arrays and fluorescence telescopes

Shower of secondary particles originates during collissions with molecules in the atmosphere.

The array of ground detectors is recording and sampling fraction of secondary particles.

Detectors of cosmic rays with ultra-high energies

7 different detectors were in operation during 40 years of measurements and achieved detection of approximately ~ 200 particles with energies over 4.10^{19} eV and only ~ 20 particles with energies over 10^{20} eV.

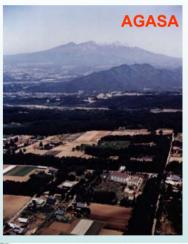

Surface detectors:

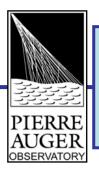

- Volcano Ranch, USA (1959 1963)
- SUGAR, Australia (1968 1979)
- Haverah Park, UK (1968 1987)
- Yakutsk, Russia (1970 today)
- AGASA, Japan (1990 2004)

Fluorescence detectors:

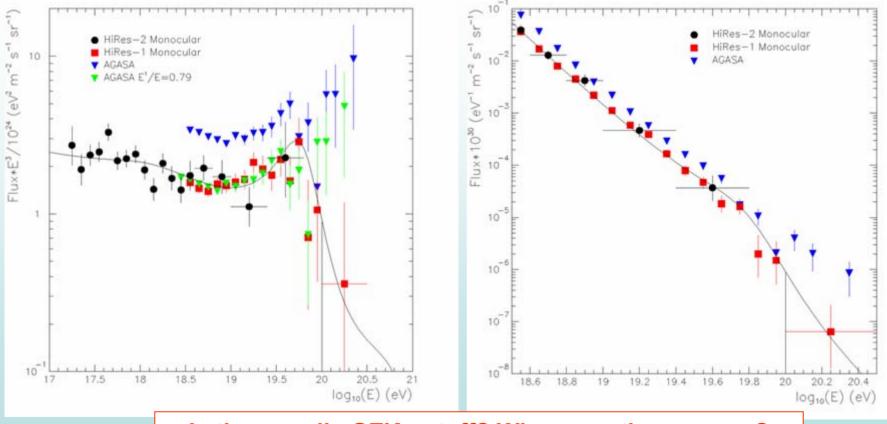

- Fly's Eye, USA (1981 1992)
- HiRes, USA (1998 2006)

GZK or not to GZK: HiRes vs. AGASA

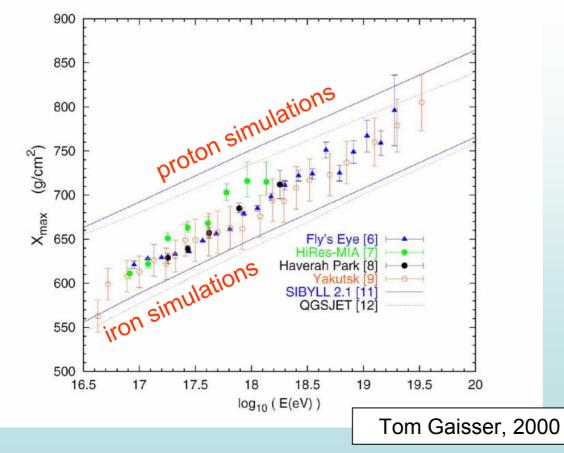

Is there really GZK-cutoff? Where are the sources?

Chemical composition of UHECR

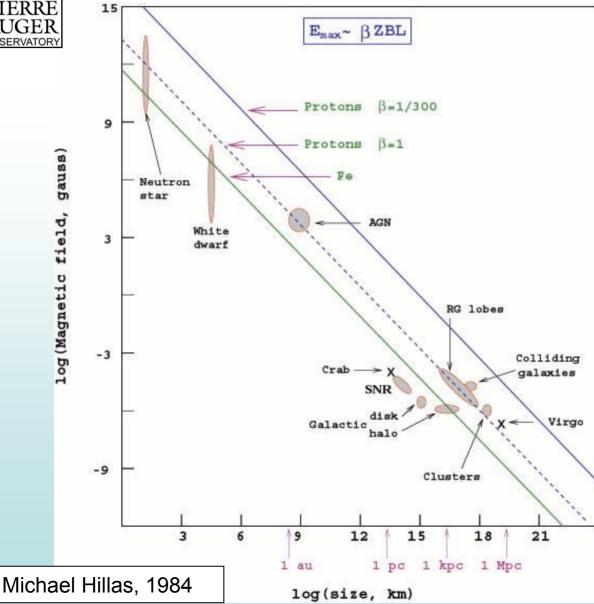

Protons, iron nuclei or mix? We (once again) don't know.

• Elongation rate (mean shower maximum in the atmosphere vs. energy) indicates the dominant chemical component, but we have to compare to simulations to interpret the data (strong model dependence !)

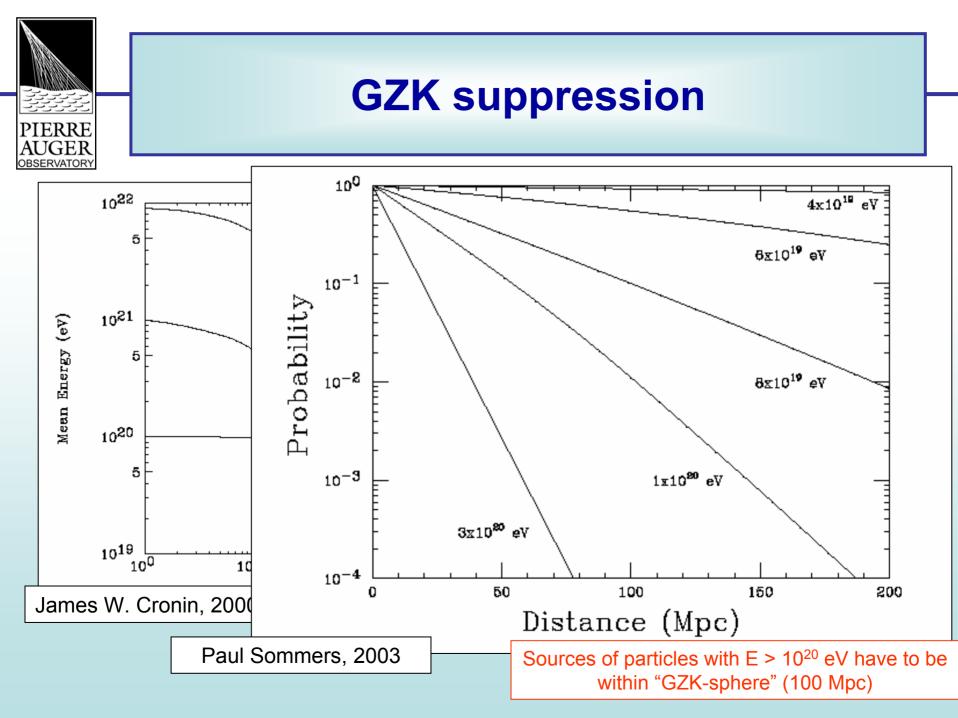

Sites of origin of UHECRs

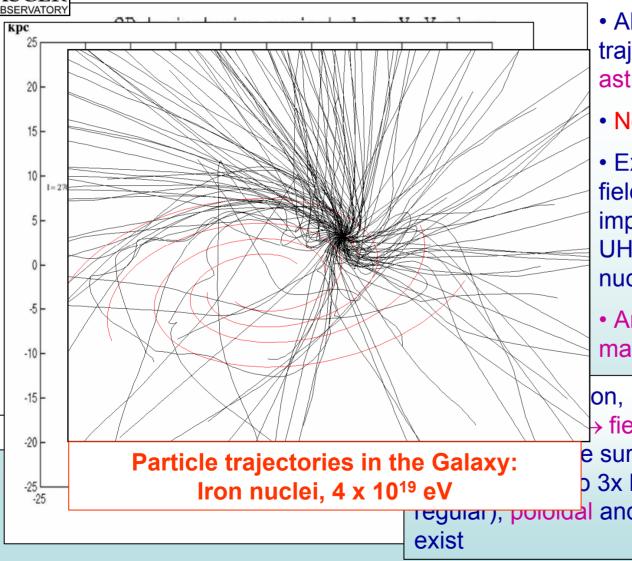

• Fermi acceleration in magnetic fields.

• We need magnetic fields extremely strong OR filling extremely large regions to accelerate particles above 10²⁰ eV.

• And still, all parameters have to be finely tuned.

Influence of magnetic fields

• Above 10¹⁹ eV - not curved trajectories ? - "Cosmic ray astronomy" ?

• Not so sure...

• Extragalactic magnetic fields could be very important, especially if UHECRs are mainly iron nuclei.

• And what about Galactic magnetic field?

on, ..., Faraday rotation

The Pierre Auger Observatory

Mendoza province, Argentina

and the second second second second

The Pierre Auger Observatory

More than 250 PhD scientists from more than 60 institutions from 15 (+2) countries.

Participating countries:

Argentina, Australia, Bolivia^{*}, Brazil, Czech Republic, France, Germany, Italy, Mexico, Netherlands, Poland, Portugal, Slovenia, Spain, United Kingdom, USA and Vietnam^{*}

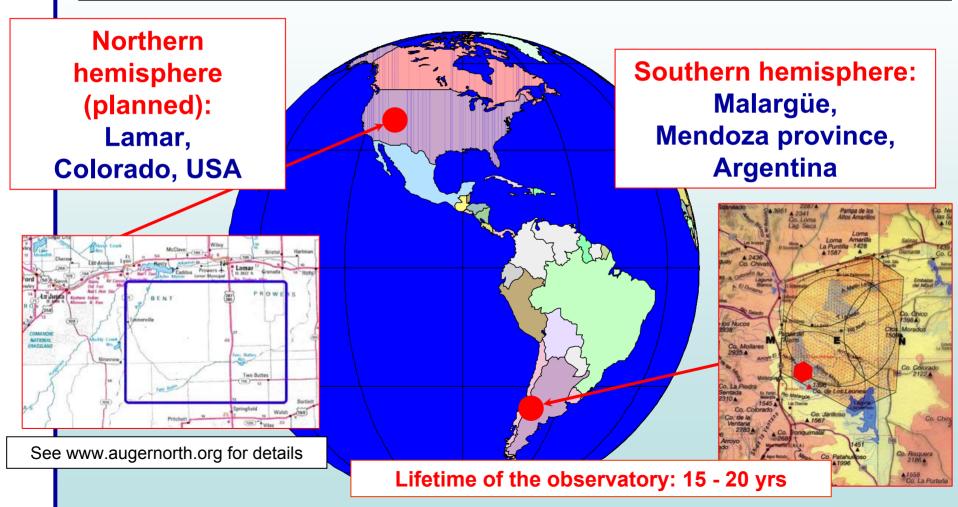

* - associated countries

Pierre Auger Observatory

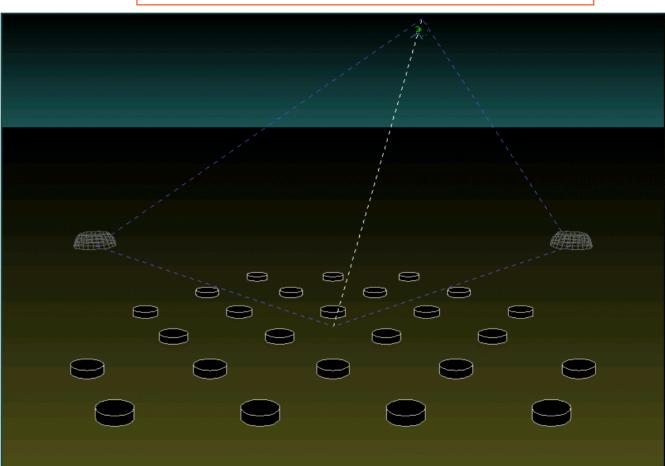

The construction of the southern site in Argentina is (almost) completed.

The Pierre Auger Observatory = hybrid detector of cosmic rays

• The array of surface Cherenkovov detectors will be accompanied with system of fluorescence telescopes, which will observe faint UV/visible light during clear nights. This fluorescence light origins as by-product during the interactions of shower particles with the atmosphere.

Scheme of hybrid detector function

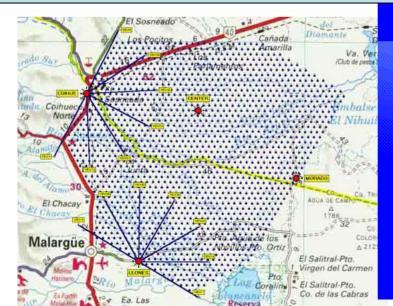

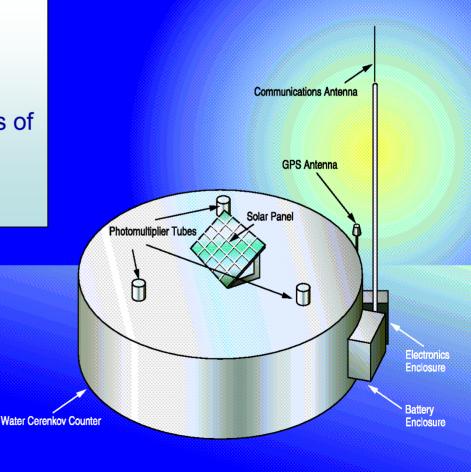

Ground detectors of the Pierre Auger Observatory

Ground detectors:

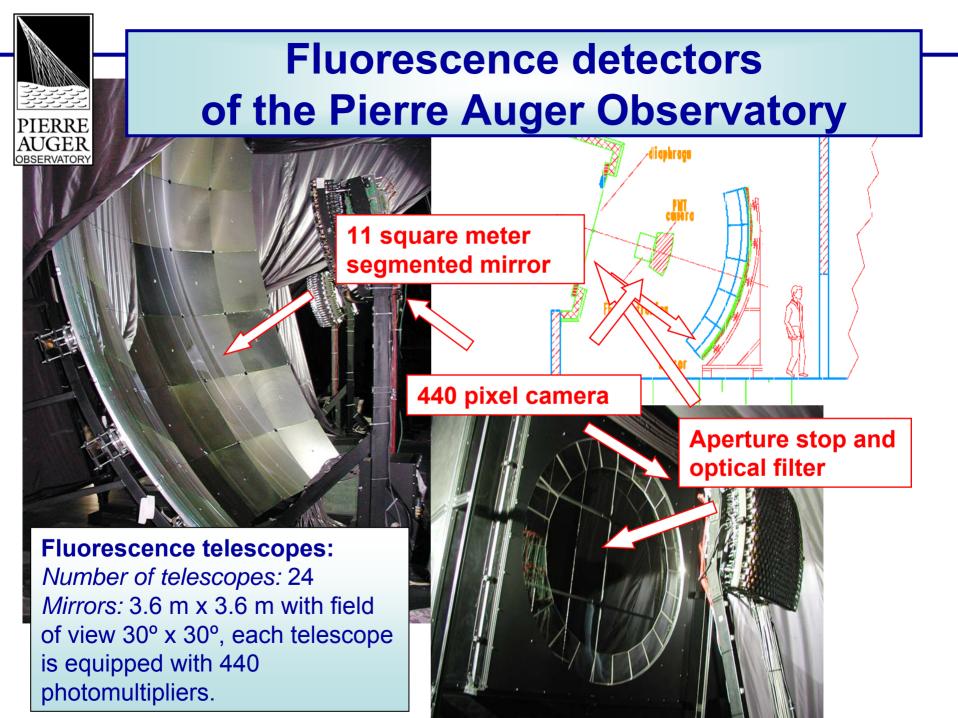

Covered surface: 3000 km² Number of detectors: 1600 Type of detector: Detector of Cherenkov radiation, each consisting of 12 000 litres of ultrapure water and equipped with 3 photomultipliers.

Spacing between detectors: 1.5 km.

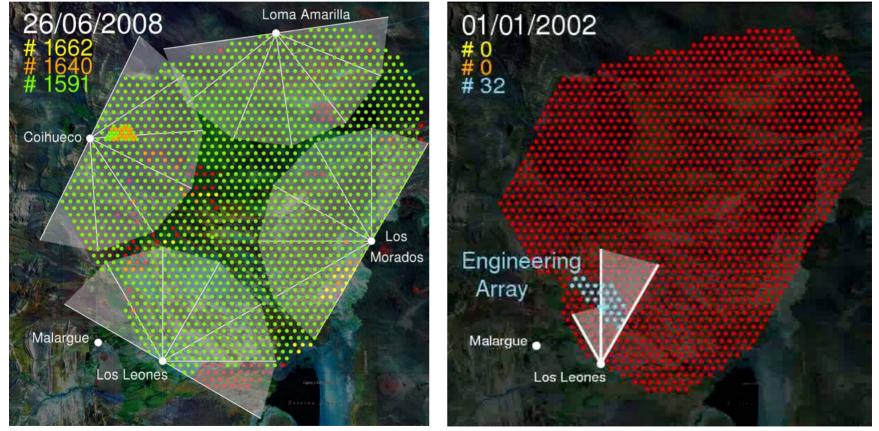

Pierre Auger Project Surface Detector Station

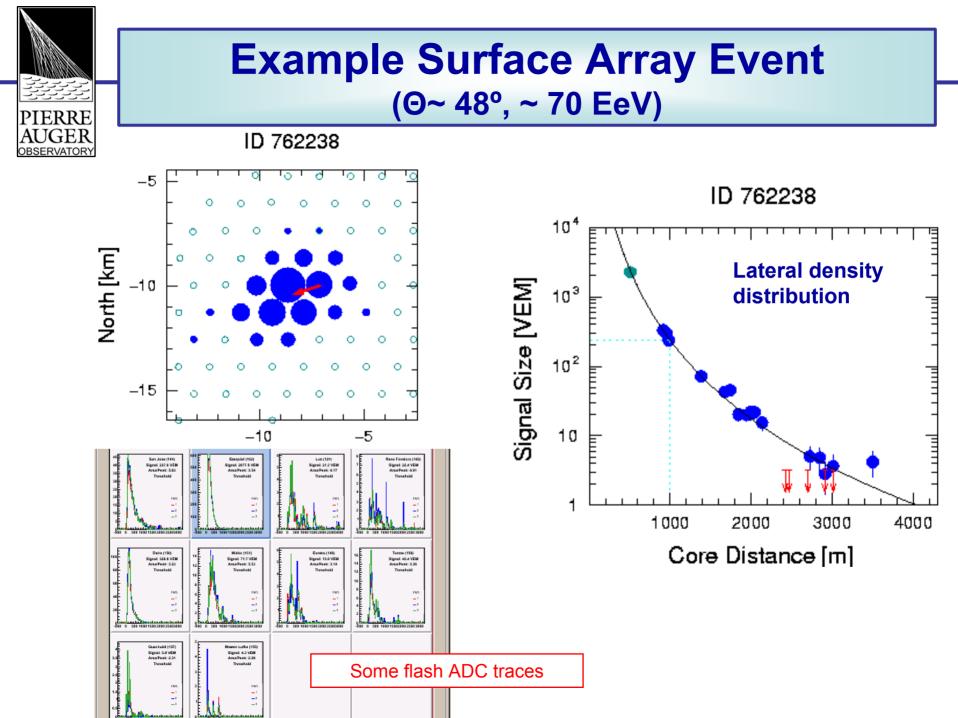

Evolution of the *hybrid detector*

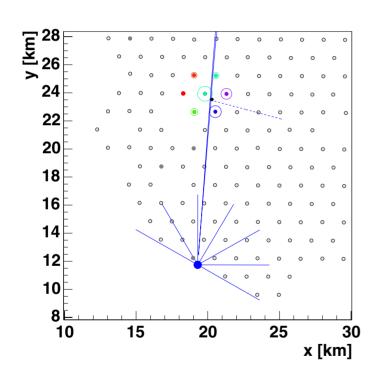

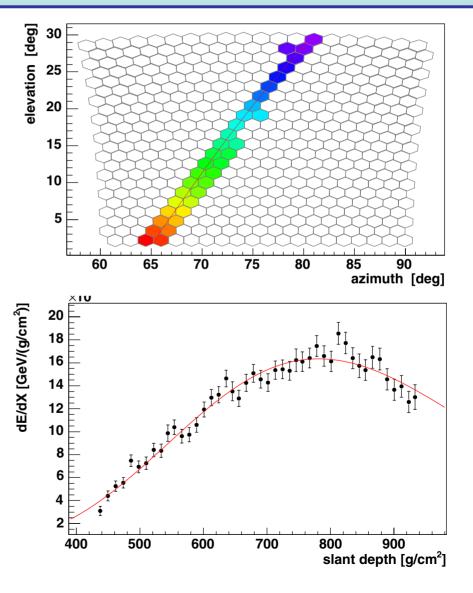

Production of scientific data since late 2003.

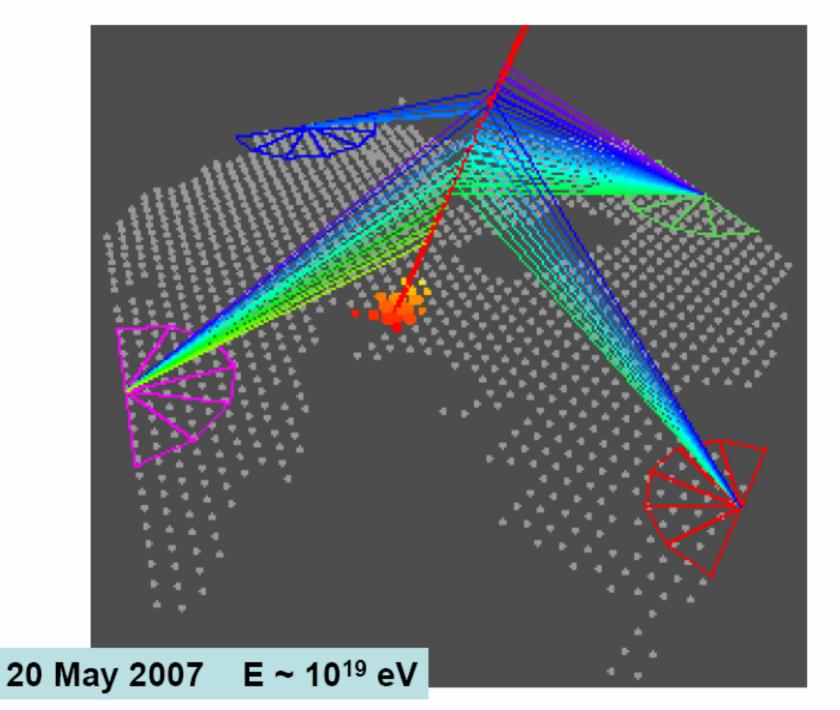

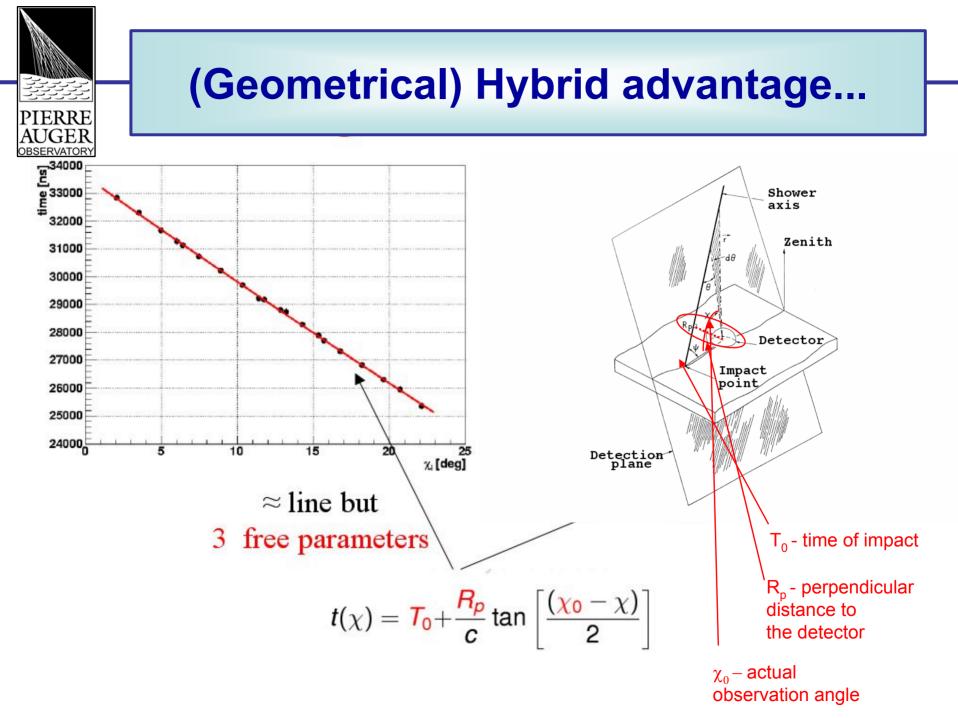

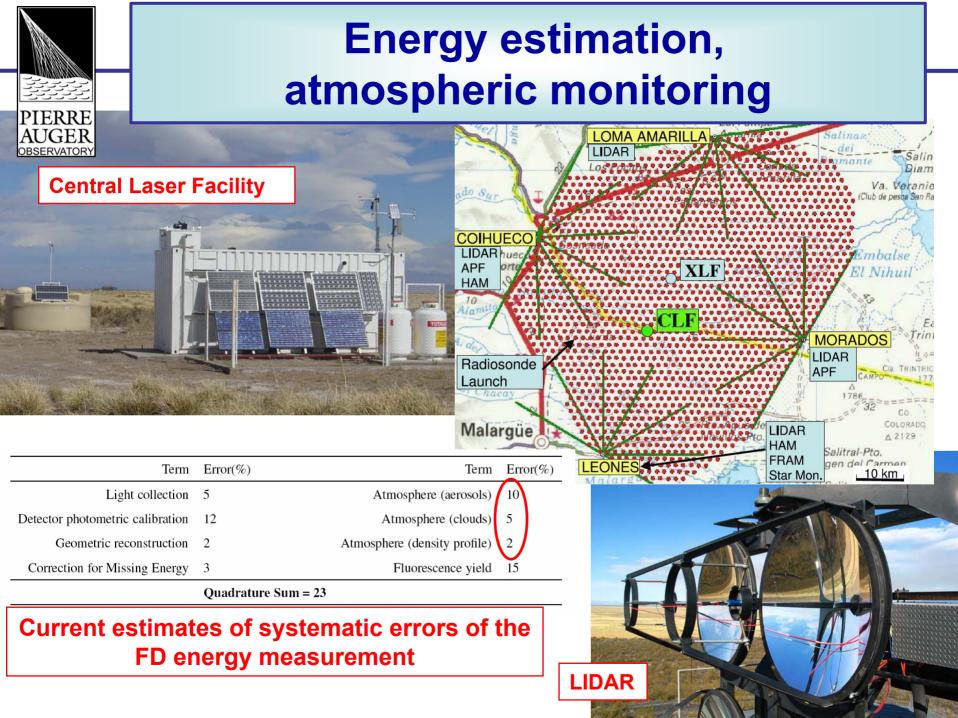

Example Hybrid Event ($\Theta \sim 30^{\circ}$, ~ 8 EeV)

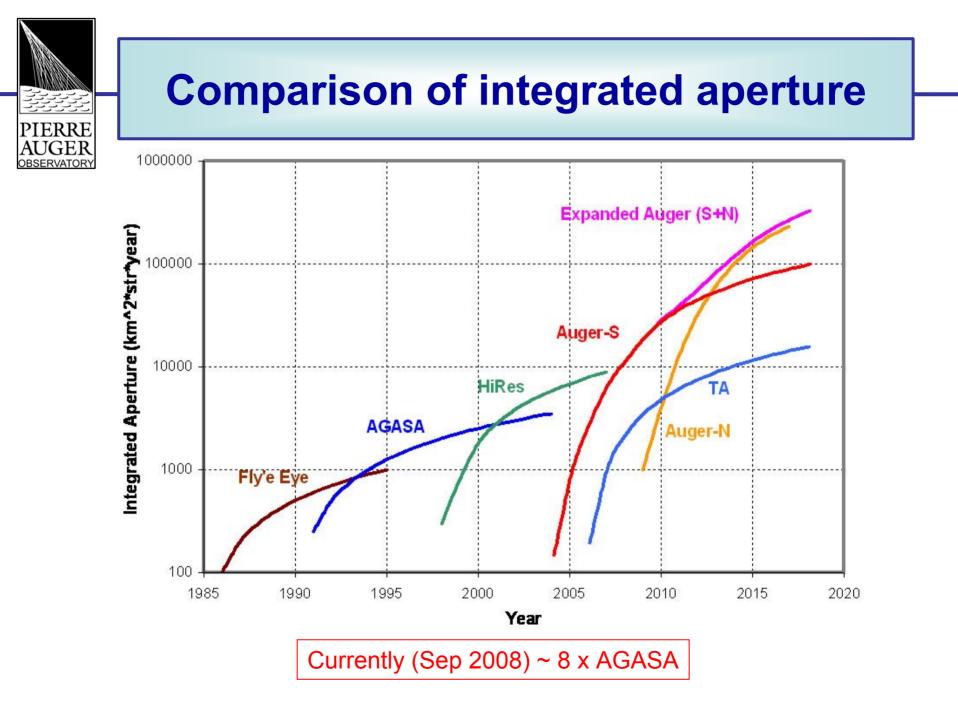

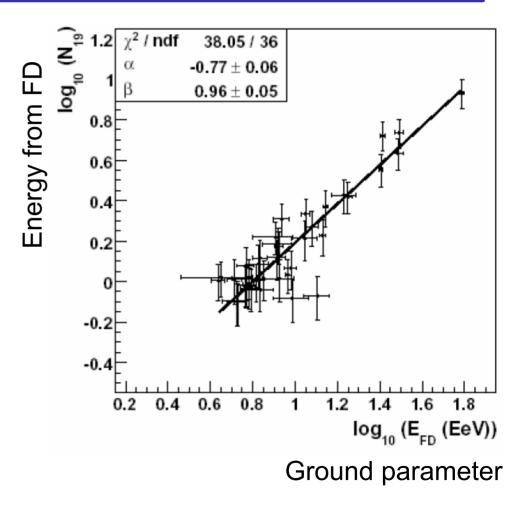

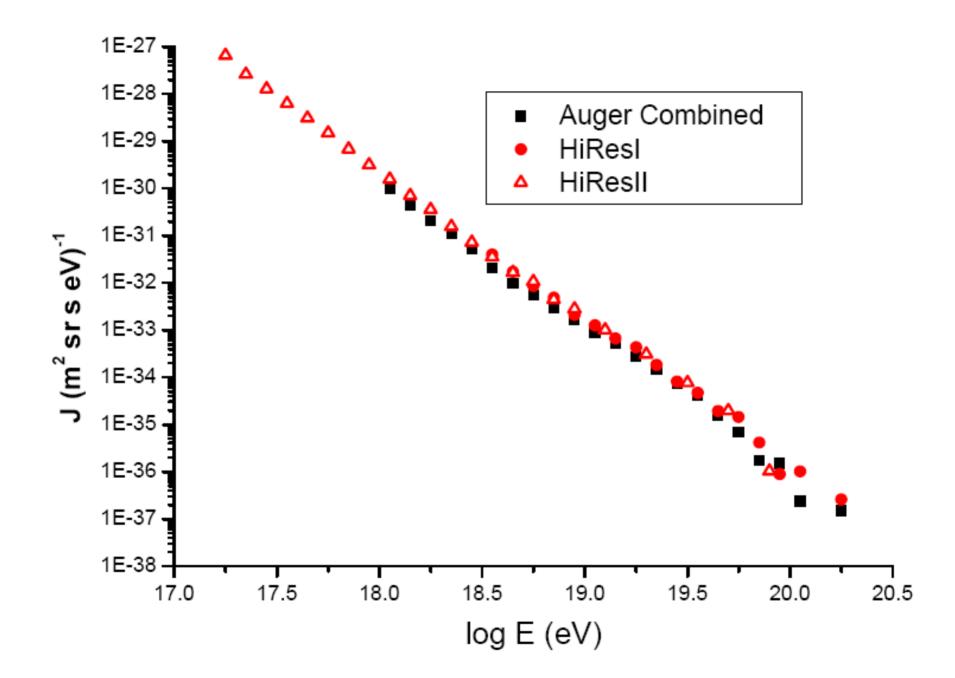

Auger Observatory results

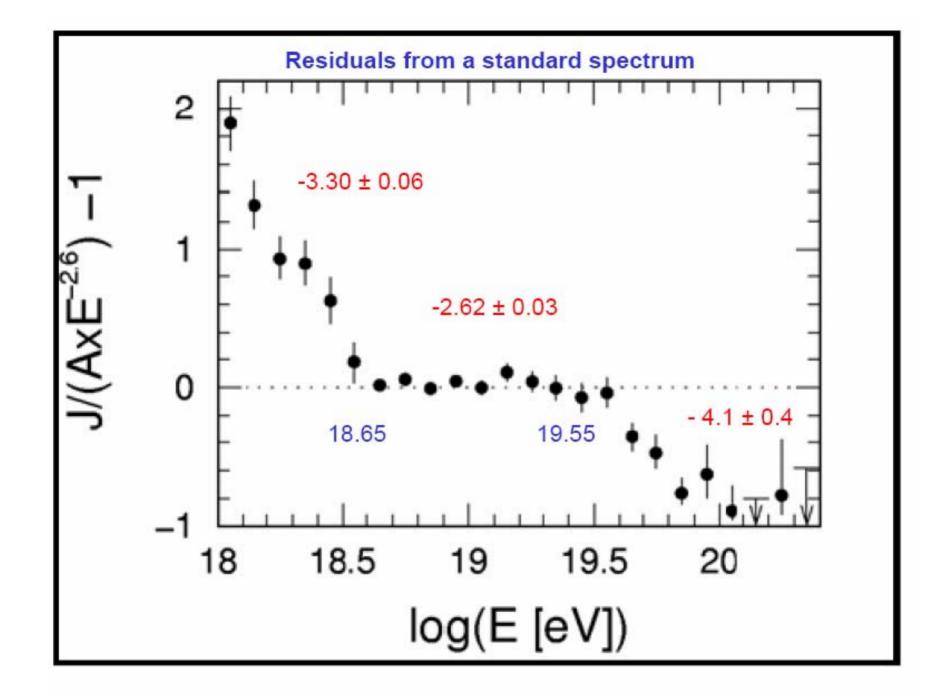

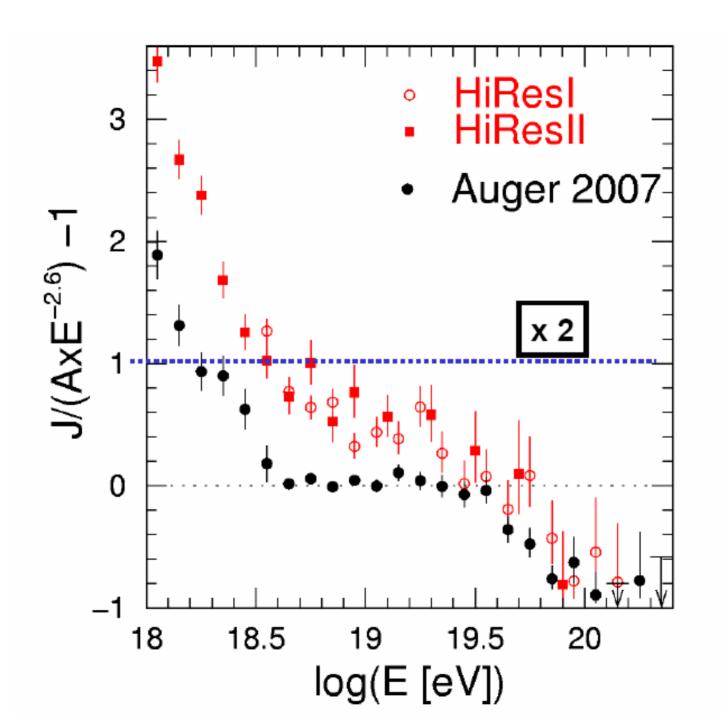

Auger Energy Spectrum

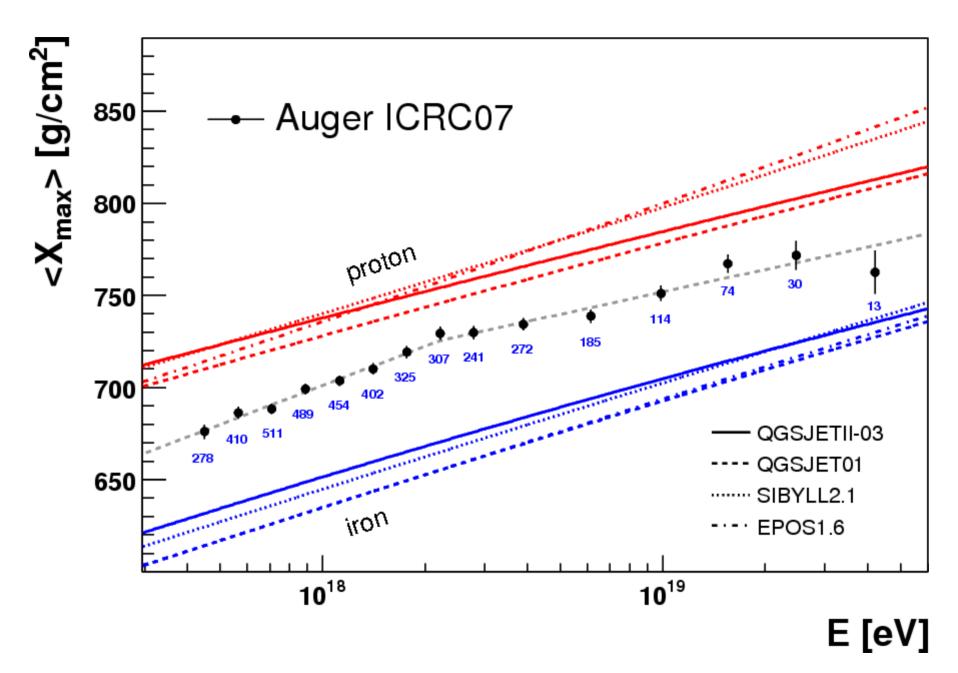

- No spectrum from SD only!
- Relation between particle density parameter S(1000) and FD energy using selected hybrid events
- Aperture from SD
- Combining advantages of FD technique (calorimetric measurement of energy) and of SD technique (well defined aperture; 100 % duty cycle)

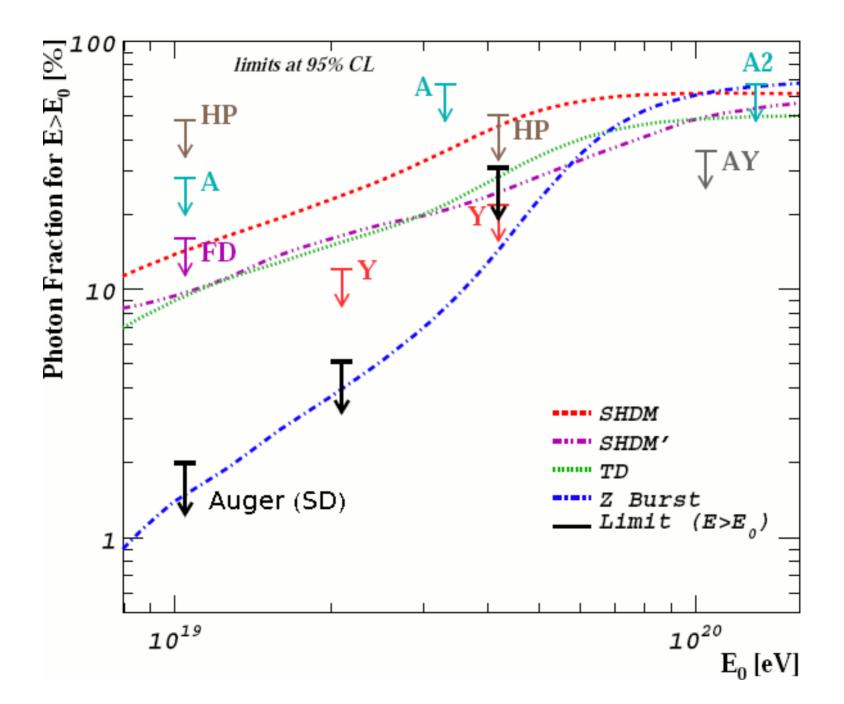

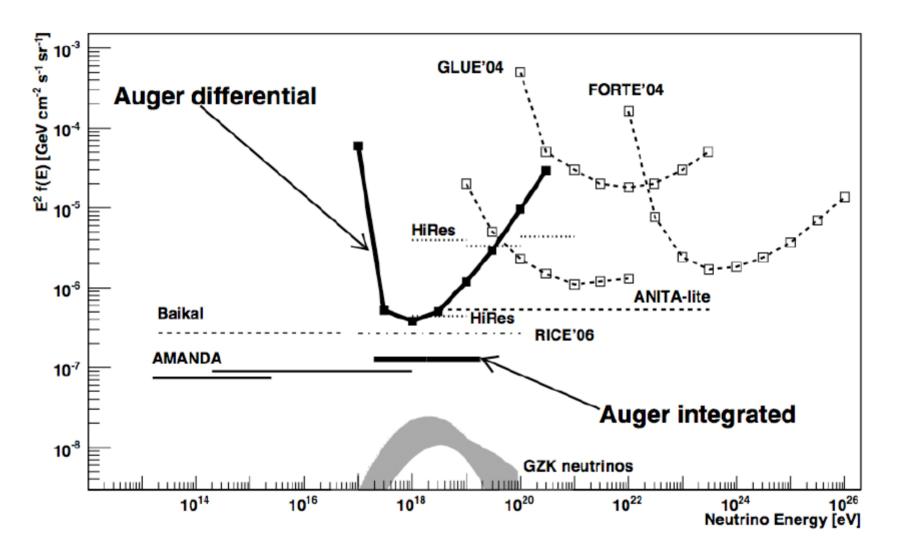

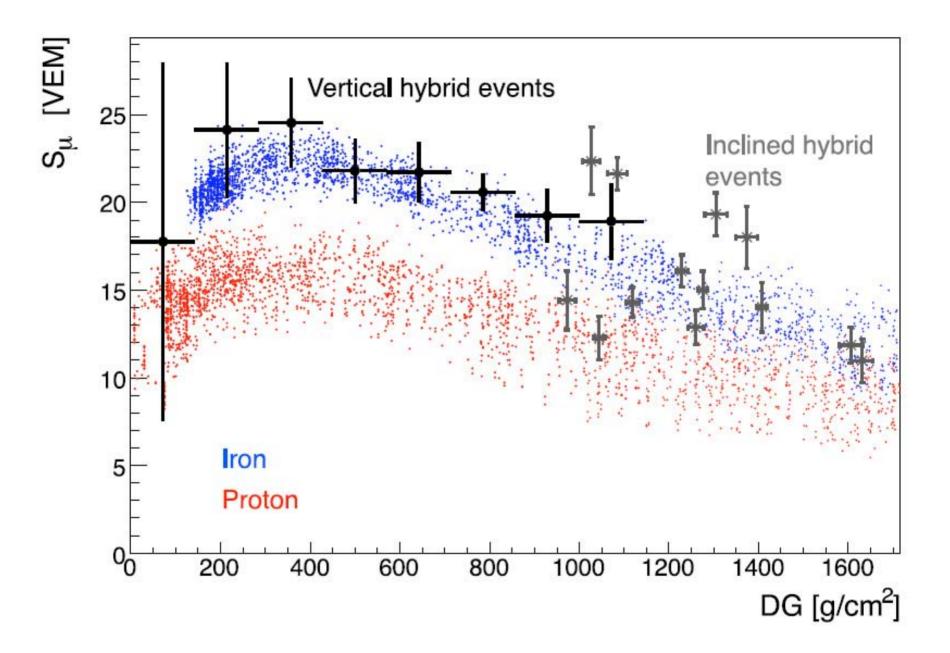

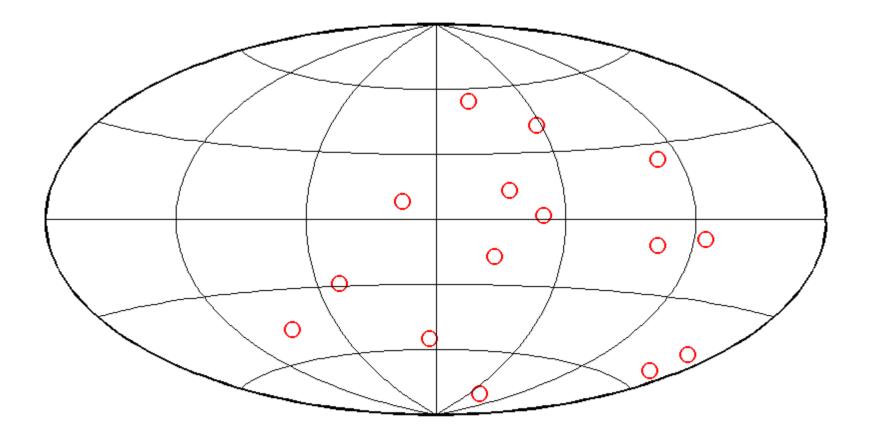

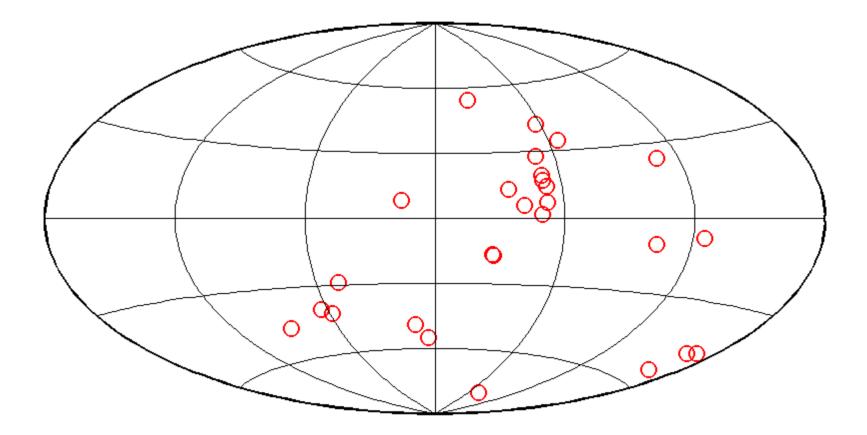

"Discovery of the year?"

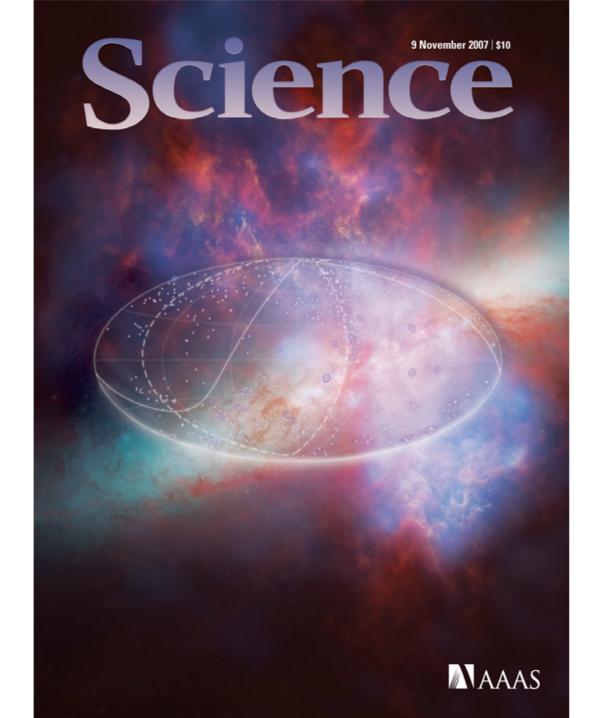

AGASA-like situation before the start of operation of the Pierre Auger Observatory

"Discovery of the year !"

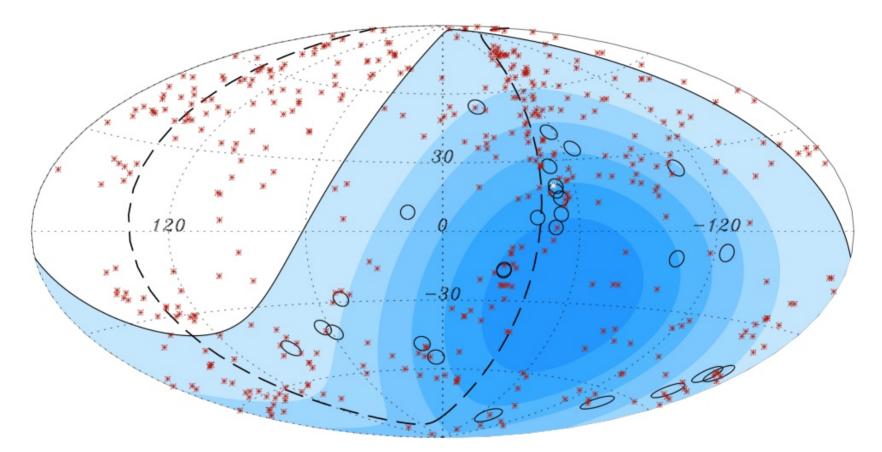

Particles with highest energies do not arrive isotropically.

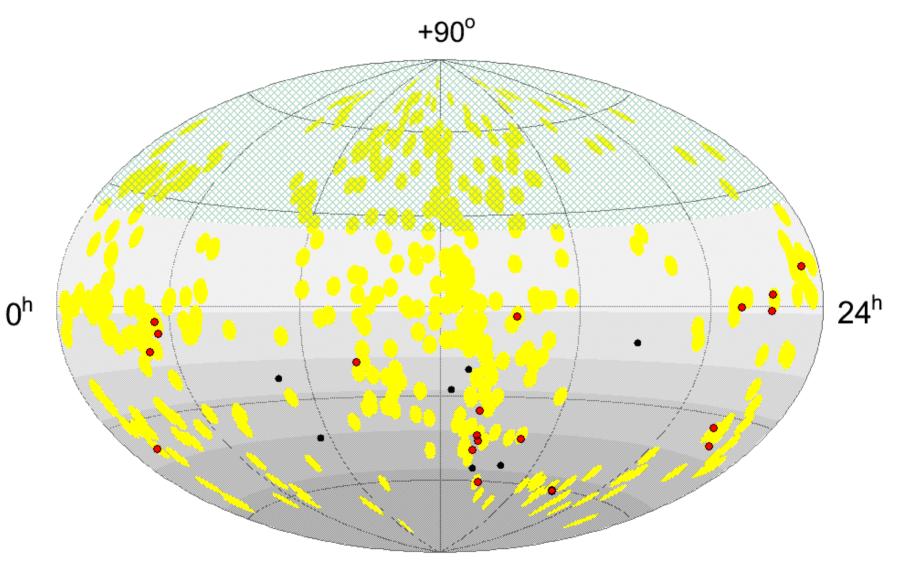

Is observed distribution in agreement with distribution of any type of known astrophysical objects?

Yes! The best agreement is with the distribution of nearby active galaxies.

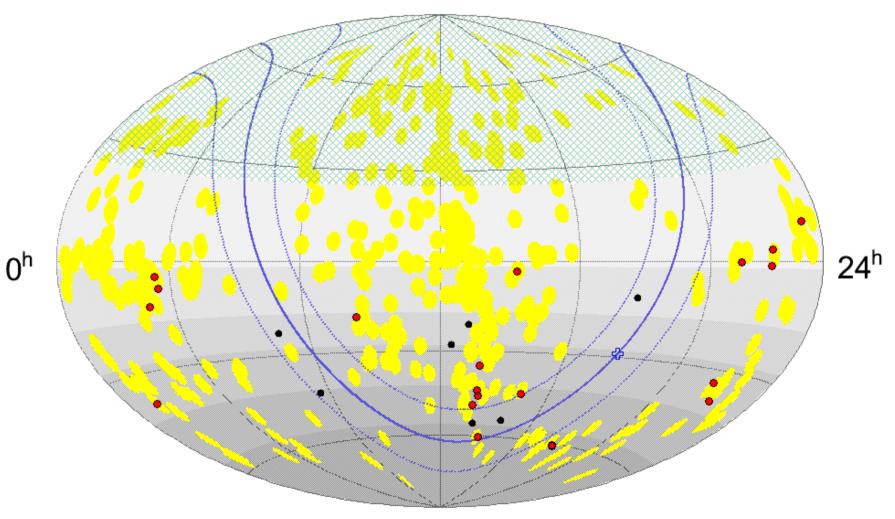

Blue – visible part of the sky Red stars – active galactic nuclei (AGNs) with distance < 75 Mpc – in agreement with our expectations (GZK cutoff)

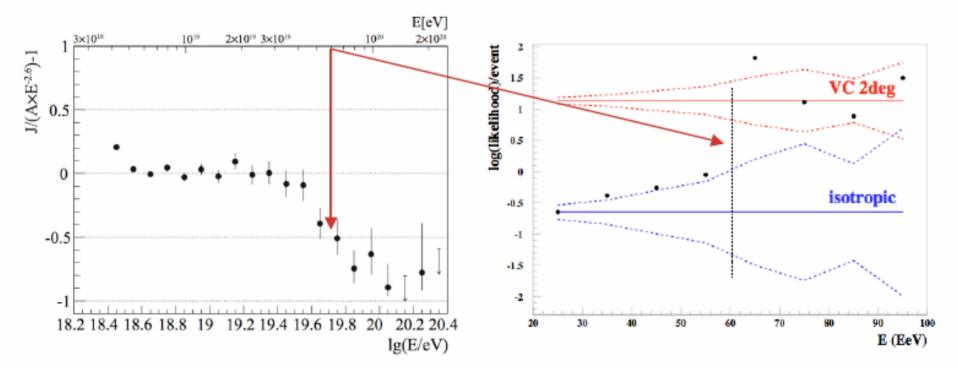

Less than 1% probability to observe such correlation by chance.

-90°

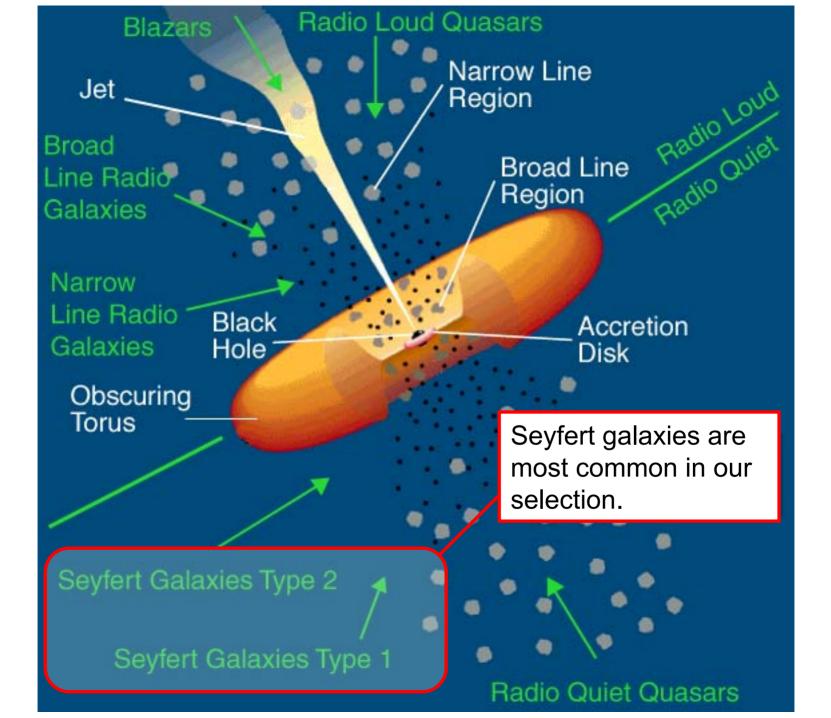

-90°

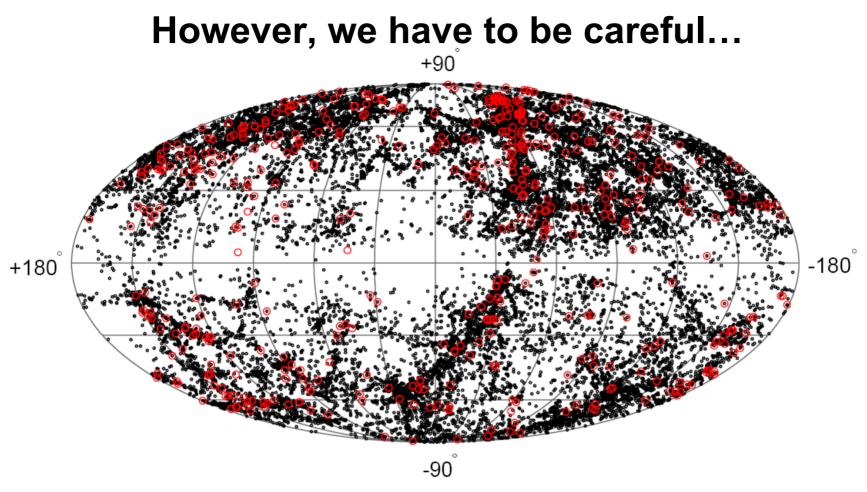

So, what are active galactic nuclei?

- galaxies with supermassive black holes in their centers; black hole mass in order of 10⁷ - 10⁸ solar masses; enough matter nearby to be swallowed

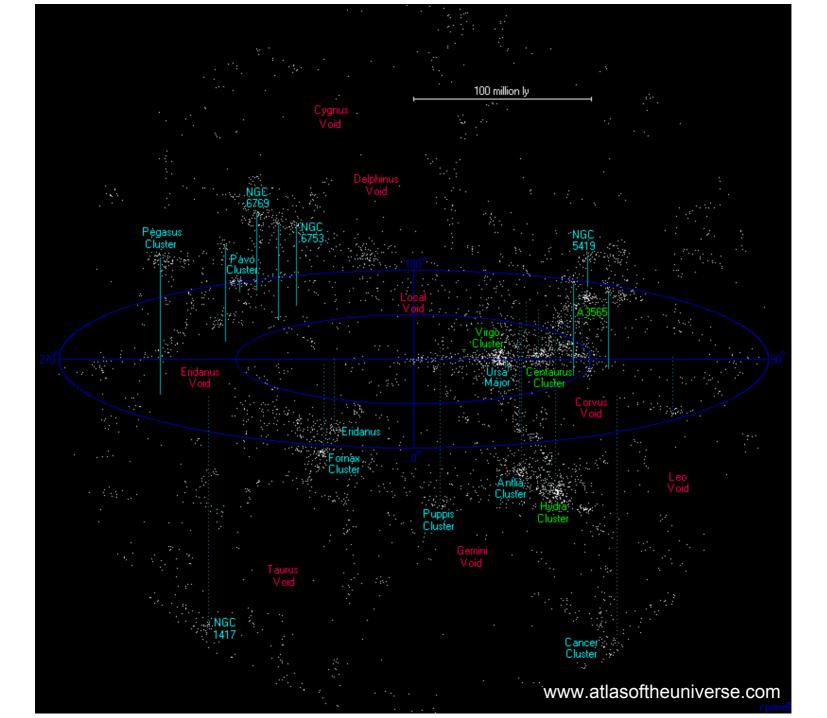

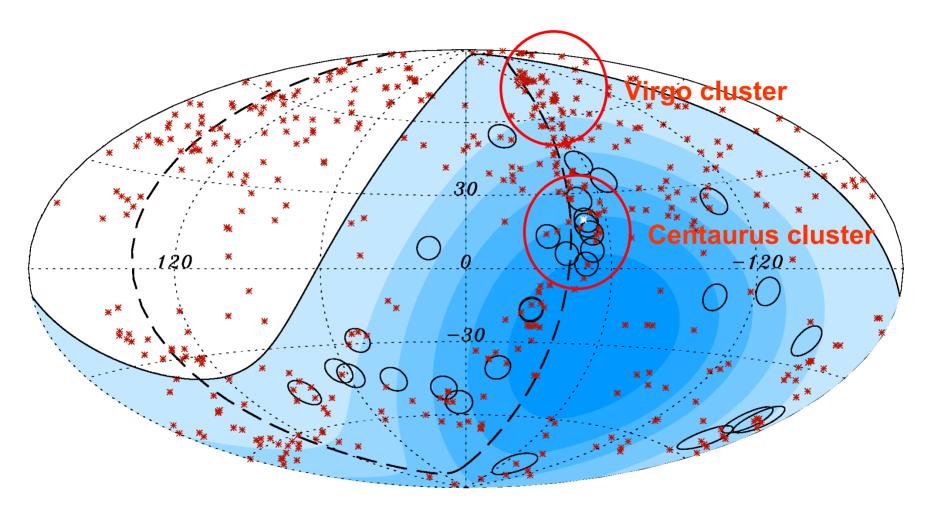

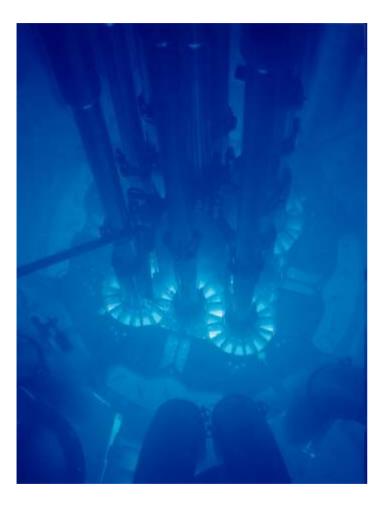

Red circles – (again) AGNs closer than 75 Mpc Black dots – all galaxies closer than 75 Mpc (HyperLEDA catalogue)

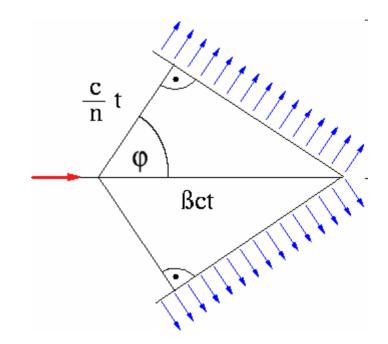

Distribution of ordinary galaxies (and matter in general) and of AGNs is very similar!

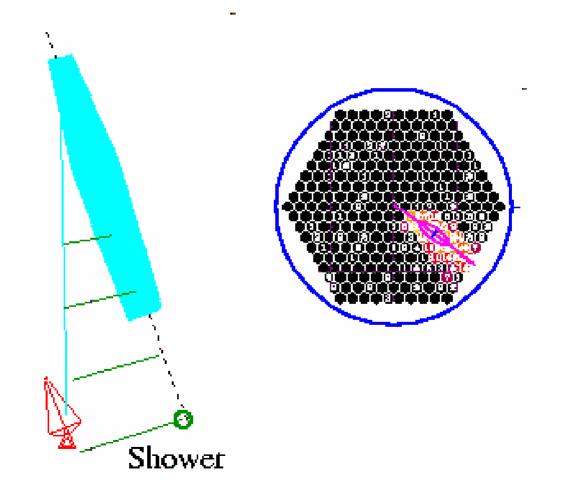

So, our first guess that the particles with the highest energies come from AGNs is not correct \rightarrow we need more data from both South and North ...
